

YOLOWISATA (INDOMIEPOOKIES) - ONE PAGER

1. Challenge Tackled

Small local tourism operators, like Noor on her coffee farm, are invisible online, can't talk to visitors who speak another language, and never learn what visitors value. YoloWisata is an offline-first website where travelers discover local businesses through a swipe-based "Travel DNA", message and book them across languages, and leave postcards that are turned into simple insights for the owner. It works for any sector: a farm, a workshop, a kitchen, a guide.

2. Tools / ML Models Used

- **Claude**: brainstorming, concept review, and frontend development.
- **Figma**: ideation boards to collect and curate ideas before building.
- **ChatGPT / OpenAI Codex**: backend integration, debugging, architecture review, and code review.
- **Cursor/Antigravity**: additional debugging and development support.
- **Entire**: navigating the codebase and coordinating across AI-assisted development workflows.
- **Supabase**: PostgreSQL database and backend data layer.
- **FastAPI**: Python backend API
- **Faster-Whisper**: local speech-to-text for business voice onboarding.
- **Qwen 2.5 1.5B Instruct**: small local model used to transform transcripts into structured experience listings.
- **llama.cpp / GGUF**: CPU-friendly local inference for Qwen.
- **ElevenLabs**: multilingual voice output where network access is available.
- **Service Worker + local browser storage**: offline-first application behavior and delayed synchronization.

3. What Worked Well

- **Interactive Travel DNA**: ten swipes produce a profile and a match score for every local business, with the reasons shown.
- **Direct connection to local businesses**: per-business chat with translation, booking requests with day and time, and a closed-day warning.
- **Offline-first**: the site reopens with no signal, and actions are queued and sent later.
- **Owner insights with evidence**: every finding shows its count, the quotes behind it, and a confidence label.

4. What Was Challenging

- A two-person team, 12 hours apart, doing this for the first time. We split the work into frontend and backend and handed over asynchronously.
- **Merging parallel work**: two people and several AI agents editing the same files caused merge conflicts, which we resolved by hand.
- **Translation without a full model**: we used a prepared phrase list and showed untranslated text honestly.
- **AI usage limits**: we hit token caps and had to wait about two hours between sessions, so we planned work around them.

5. Working plan - How We Spent Our Time

Hours	Work	Team
0-2	Brainstorming, user flow, and architecture	Olip: ideas and concept, frontend design, video editing, feedback. Esme: ideas and concept, backend and integration.
2-6	Frontend and backend development in parallel	
6-14	Integration, Supabase, voice AI, offline sync, and debugging	
14-20	Testing, Plan My Day, polish, demo, and submission	

6. Optional Additions:

If we had 24 more hours, we'd... go insane and pray that our computer wouldn't crash.
